

1. DNS #1 (dig)

- DNS reconnaissance

- Use dig to query the local DNS server for the A record of www.sou.edu using TCP. Then, use dig to do the same for the MX record of sou.edu.

```
branden@branden-VirtualBox:~$ dig www.sou.edu A tcp

; <<>> DiG 9.16.1-Ubuntu <<>> www.sou.edu A tcp
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 56937

branden@branden-VirtualBox:~$

```

Running commands

- dig www.sou.edu A tcp
- Dig sou.edu MX

- When a web request hits port 80 of 131.252.220.66, how does the server know which site to serve from? (i.e. what protocol header)
 - Port 80 is a known port for http, this in conjunction with DNS tells the server which site to serve from.

- DNS iterative lookups
 - On your VM simulate the operation of a local DNS server. Choose a DNS name containing at least 4 parts (e.g) www.inside.sou.edu, console.cloud.google.com, www.unsw.edu.au, www.amazon.co.uk)
 - Dig to get ip

```
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984$ dig f.root-servers.net
```

```
; <<>> DiG 9.16.1-Ubuntu <<>> f.root-servers.net
;; global options: +cmd

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984$

```

Examine the man page for `dig` to find the flag for doing simplified reverse lookups on IPv4 addresses. Given the flag and the shell tutorial above, perform the following and include the results in your lab notebook:

- The flag for simplified reverse lookup is `-x`, `-4` for only ipv4 addresses
- Use a single command line with commands `dig`, `egrep`, and `awk`, to list all IPv4 addresses that `espn.go.com` points to.
 - `dig espn.go.com -x -4 | egrep 99 | awk '{print $5}'`

```

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984$ dig espn.go.com | egrep 99 | awk '{print $5}'
99.86.35.90
99.86.35.95
99.86.35.96
99.86.35.52
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984$

```

- Take that list and create a single for loop in the shell that iterates over the list and performs a reverse lookup of each IP address to find each address's associated DNS name. As with the previous step, pipe the output of the for loop to `egrep` and `awk` so that the output consists only of the DNS names.
 - Set `X=`dig espn.go.com -x -4 | egrep 99 | awk '{print $5}'``
 - Then `for i in `echo $X`; do dig -x $i; done | egrep server | awk '{print $5}'`

3. Host Enumeration

- On your VM, practice some more shell (bash) preliminaries.
- Ranges in the shell can be specified via { } notation. Perform the following two commands to see how it works.

```
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984$ echo {0..2}{0..9}
00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984$ for i in {1..20}
> do
>   echo $i
> done

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984$
```

- Using a for loop, perform a reverse DNS lookup for each IP address on the 131.252.220.0/24 subnet. Note that some addresses on the subnet do not have names bound to them and will not return a record.
- Take the output of the loop and pipe it to `egrep` and `awk` to list just the names of the hosts, then redirect the final output to a file called `220hosts.txt` output using the `>` character to perform output redirection to a file.
 - `for i in {0..255}; do dig -x 131.252.220.$i; done | egrep -A1 "ANSWER SECTION" | awk '{print $5}' | egrep -v '^$' >> 220hosts.txt`

```

4. DNS #2 (Geographic DNS)

- What geographic locations do ipinfo.io and DB-IP return?
 - 131.252.208.53

Geolocation data from ipinfo.io (Product: API, real-time)

IP Address	Country	Region	City
131.252.208.53	United States 	Oregon	Portland
ISP	Organization	Latitude	Longitude
Portland State University	Portland State University (pdx.edu)	45.5234	-122.6762

Geolocation data from [DB-IP](https://db-ip.com) (Product: Full, 2021-1-1)

IP Address	Country	Region	City
131.252.208.53	United States 	Oregon	Portland
ISP	Organization	Latitude	Longitude
Portland State University	Portland State University	45.5231	-122.676

- 198.82.247.66

Geolocation data from [ipinfo.io](#) (Product: API, real-time)

IP Address	Country	Region	City
198.82.247.66	United States 	Virginia	Blacksburg
ISP	Organization	Latitude	Longitude
Virginia Polytechnic Institute and State Univ.	Virginia Polytechnic Institute and State Univ. (vt.edu)	37.2296	-80.4139

Geolocation data from [DB-IP](#) (Product: Full, 2021-1-1)

IP Address	Country	Region	City
198.82.247.66	United States 	Virginia	Blacksburg (Farmview - Ramble)
ISP	Organization	Latitude	Longitude
Virginia Polytechnic Institute and State Univ.	Virginia Polytechnic Institute and State Univ.	37.2037	-80.4143

Then, using dig, resolve [www.google.com](#) from each of the DNS servers (dig @<DNS_server_IP> [www.google.com](#)).

- Record each result for your lab notebook.
 - Issue with first dig, refused
 - Second dig no issues

```

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$ dig @131.252.208.53 www.google.com

Google LLC	Google LLC	37.422	-122.084

- All had the same location

- What is the geographic distance between each pair of DNS server and web server?
 - Portland Oregon to Mountain view California is 667.2 miles
 - Blacksburg Virginia to Mountain view California is 2685.5 miles

Perform a traceroute to all 4 IP addresses from your network.

- Do the routes reveal any information on the accuracy of the geographic locations given? (Answer might be no)
 - The lab suggests 4 ips, however I had 6. Also when performing traceroute on any of these 6 ips gives me no information. Possibly another issue here.

```
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$ traceroute 172.253.62.147
traceroute to 172.253.62.147 (172.253.62.147), 30 hops max, 60 byte packets

    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 10868 bytes 789783 (789.7 KB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$

```

- Use `netstat` to find the IP address of the default router

```

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$ netstat -r
Kernel IP routing table
Destination      Gateway         Genmask         Flags   MSS Window  irtt Iface
default          _gateway       0.0.0.0         UG      0 0        0 enp0s3
10.0.2.0         0.0.0.0        255.255.255.0   U       0 0        0 enp0s3
link-local       0.0.0.0        255.255.0.0     U       0 0        0 enp0s3
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$

```

- Temporarily change the default DNS server by performing `sudo vim /etc/resolv.conf` and changing the IP address of the nameserver to `1.1.1.1`. Note that this will be overwritten upon next DHCP renew

```
branden@branden-VirtualBox: ~/cs356-w21-branden-codd-940428984/lab02
# This file is managed by man:systemd-resolved(8). Do not edit.
#
# This is a dynamic resolv.conf file for connecting local clients to the
# internal DNS stub resolver of systemd-resolved. This file lists all
# configured search domains.
#
# Run "resolvectl status" to see details about the uplink DNS servers
# currently in use.
#
# Third party programs must not access this file directly, but only through the
# symlink at /etc/resolv.conf. To manage man:resolv.conf(5) in a different way,
# replace this symlink by a static file or a different symlink.
#
# See man:systemd-resolved.service(8) for details about the supported modes of
# operation for /etc/resolv.conf.

nameserver 1.1.1.1
options edns0 trust-ad
~
~
~
~
~
~
~
```

- Perform a reverse DNS lookup on the DNS server to find its name

```
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$ dig -x 1.1.1.1

; <<>> DiG 9.16.1-Ubuntu <<>> -x 1.1.1.1

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$
```

Dump ARP table

- To begin with, we will use the shell to delete all entries in the ARP table for the VM. Examine the output of the command below to see all of the entries in the table and their numeric IP addresses.

```
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$ arp -an
? (10.0.2.2) at 52:54:00:12:35:02 [ether] on enp0s3
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$
```

- Use a single command-line to create a file that contains each IP address that appears in the machine's ARP table and places the results in a file called `arp_entries`.
 - `arp -an | awk -F '[]' '{print $2}' > arp_entries`

```

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$ arp -an | awk -F '[]' '{print $2}' > arp_entries
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$ cat arp_entries
10.0.2.2
branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$

```

6. Collect and analyze the network trace of a connection

- Clear ARP table and retrieve site

Analyze trace

Stop the packet capture and inspect it. Ensure the ARP packets and DNS request and response packets for the request show up in the trace. If not, you are using a cached lookup.

- Take a screenshot of the trace within Wireshark and include an annotation of the packets in the trace to explain the purpose of each of the packets being exchanged.

The terminal window on the left shows the following commands and output:

```

branden@branden-VirtualBox:~/cs356-w21-branden-codd-940428984/lab02$ for i in $(cat arp_entries); do sudo arp -d $i; done; wget https://inside.sou.edu/
--2021-01-21 17:25:58-- https://inside.sou.edu/
Resolving inside.sou.edu (inside.sou.edu)... 140.211.99.30

The packet details pane shows the structure of the selected ARP request packet (No. 1):

```

Frame 1: 42 bytes on wire (336 bits), 42 bytes captured (336 bits) on interface enp0s3, id 0
Ethernet II, Src: PcsCompu_2b:d1:39 (08:00:27:2b:d1:39), Dst: Broadcast (ff:ff:ff:ff:ff:ff)
Address Resolution Protocol (request)

```

- Little confused here on what is being asked. Slack says to answer for a ping but we only captured packets through wireshark
- 1 and 2 are an ARP request and an ARP response
- 3-6 are DNS queries to <https://inside.sou.edu> and then a response
- After that we have a TCP 3 way handshake
- Then a bunch of TCP and TLSv1.2 for https connection and encryption key exchange.

- How many DNS requests are made?
 - There are 2 DNS requests made
- How many TCP connections does the browser initiate simultaneously to the site?
 - There are 2
- How many HTTP GET requests are there for embedded objects?
 - Need to redo wireshark capture. Per original instructions we went through <https://inside.sou.edu> which is encrypted.
 - After re running with <http://inside.sou.edu> we see one get, but it's just attempting to go to <https://inside.sou.edu>.
